

$$y = ax^2 + c$$

This is a Quadratic Function in Standard Form where $b=0$

1. when $b=0$ LOS is always $X=0$
2. This means the parabola hasn't shifted either left or right.
3. But, it has shifted up/down exactly c units.
If c is Pos it has shifted up
If c is Neg it has shifted down.
4. This is the one case where the y-int and the vertex are the same point.

$y = x^2$ is the Parent Quadratic Function

The first two "good points" to the right of the Vertex for the Parent Function are:

First "Good Point"

"1 right then 1 up"

Second "Good Point"

"2 right then 4 up"

$$y = ax^2 + bx + c$$

a tells us if a parabola opens up or down.

It's also a Vertical Stretch or Shrink Factor.

$y = x^2$ is the Parent Quadratic Function

How is the graph of $y = 2x^2$ related to the Parent Function?

Two times taller than the Parent Function

Becomes 1st good point

Becomes 2nd good point

What will $y=3x^2$ look like?

1st good pt becomes

3 times
taller than
the Parent
Function

2nd good pt becomes

What will $y=0.5x^2$ look like?

Half as tall as the Parent Function.

Parent
Function

$$\begin{array}{|c} 1 \\ \hline 1 \end{array} \times .5$$

This Function

$$\begin{array}{|c} .5 \\ \hline 1 \end{array}$$

$$\begin{array}{|c} 4 \\ \hline 2 \end{array} \times .5$$

$$\begin{array}{|c} 2 \\ \hline 2 \end{array}$$

Without using a table of values
graph the equation below
using at least 5 points. $y = -4x^2$

Since both b and c are zero this parabola
hasn't shifted horiz or vert. The vertex is still
the origin. Now use the vertical stretch factor
($a = -4$) to find the two points on one side
of the vertex then reflect them over the LOS.

Parent
Function

$$\begin{array}{|c} 1 \\ \hline 1 \end{array} \times -4$$

This Function

$$\begin{array}{|c} -4 \\ \hline 1 \end{array}$$

$$\begin{array}{|c} 4 \\ \hline 2 \end{array} \times -4$$

$$\begin{array}{|c} -16 \\ \hline 2 \end{array}$$

the equation of a Quadratic is:

$$y = 2x^2 - \boxed{} + \boxed{}$$

The vertex of this parabola is (3, -4)

Graph the rest of this parabola.

Plot the vertex then use the
vertical stretch factor ($a = 2$) to
find the two points on one side
of the vertex then reflect them
over the LOS

Parent
Function

$$\begin{array}{|c} 1 \\ \hline 1 \end{array} \times 2$$

This Function

$$\begin{array}{|c} 2 \\ \hline 1 \end{array}$$

$$\begin{array}{|c} 4 \\ \hline 2 \end{array} \times 2$$

$$\begin{array}{|c} 8 \\ \hline 2 \end{array}$$

the equation of a Quadratic is: $y = -3x^2 \square + \square$

The vertex of this parabola is (1, 5)

Graph the rest of this parabola.

Plot the vertex then use the vertical stretch factor ($a = -3$) to find the two points on one side of the vertex then reflect them over the LOS

Parent Function

$$y = x^2$$

This Function

$$y = -3x^2$$

$$y = 4x^2$$

$$y = -\frac{1}{2}x^2$$

You can now finish Hwk#4

Practice Sheet

Sec 5-2

$$y = ax^2 + bx + c$$

What does a tell us about the parabola?

- if the parabola opens up or down
- It is also a Vertical stretch or shrink factor.

What does b tell us about the parabola?

It affects the Horizontal position

What does c tell us about the parabola?

- the y-intercept
- it affects the vertical position.

If $b=0$, this it is the exact vertical translation.

If $b \neq 0$ it is **not** the exact vertical translation

What is the equation for the LOS of this quadratic?

$$y = ax^2 + c \quad x = 0$$

What is the equation for the LOS of this quadratic?

$$y = ax^2 + bx + c$$

$$\text{LOS: } x = \frac{-b}{2a}$$

Find the equation for the LOS for each quadratic function.

1. $y = 2x^2 + 18x - 14$

$$X = \frac{-18}{2(2)} = -4.5$$

3. $y = 8.7x^2 - 20$

$$X = \frac{0}{2(8.7)} = 0$$

2. $y = -\frac{1}{2}x^2 - 24x + 37$

$$X = \frac{24}{2(-\frac{1}{2})} = \frac{24}{-1} = -24$$

What is the equation for the LOS?

$$y = -3x^2 + 12x - 22$$

$$X = \frac{-12}{2(-3)} = \frac{-12}{-6} = 2$$

what can you now find?

The Vertex. Since the Vertex is a point on the LOS the x-coordinate of the Vertex is the same as the LOS. To find the y-coordinate of the Vertex you just evaluate the quadratic equation using the x-coordinate

$$(2, -10)$$

$$-3(2)^2 + 12(2) - 22$$
