

## Dear Family,

Your child is learning to understand linear functions.

A function is a relationship between two quantities where one quantity depends on the other. Functions can be either linear (the graph is a straight line with a constant rate of change) or non-linear (the graph is not a straight line and the rate of change is not constant).

**Linear**

Suppose that a local movie theater charges \$5 per ticket. Each point represents the total cost,  $y$ , for a certain number of tickets,  $x$ . The function is linear because the points form a line.

**Non-Linear**

The theater has a special “buy one get one free” offer. The tickets are still \$5, but for each ticket purchased the next ticket is free. Notice that the points do not form a line, so the function is not linear.

**Consider this problem:**

The theater offers a membership where members pay a fee of \$50 to get discounted rates for movie tickets. The table shows the cost of tickets for a member. Is the function linear?

Number of Tickets	0	1	2	3	4	5
Cost (\$)	50	53	56	59	62	65

On the next page you will see some of the ways your child will learn to approach the problem.

## Understand Linear Functions: Sample Solution

Is the function represented by the table a linear function?

Number of Tickets	0	1	2	3	4	5
Cost (\$)	50	53	56	59	62	65

**One way:** Use the table.

The rate of change is the ratio of the change in  $y$ , in this case the cost of the tickets, to the change in  $x$ , in this case the number of tickets purchased. The table shows that the rate of change is 3.

Number of Tickets	0	1	2	3	4	5
Cost (\$)	50	53	56	59	62	65

$\xrightarrow{+1} \xrightarrow{+1} \xrightarrow{+1} \xrightarrow{+1} \xrightarrow{+1}$   
 $\xrightarrow{+3} \xrightarrow{+3} \xrightarrow{+3} \xrightarrow{+3} \xrightarrow{+3}$

The rate of change is constant, so the function is linear.

**Another way:** Use a graph.

The graph of a linear function is a line. Plot the pairs of values from the table as points with the number of tickets as  $x$  and the cost of the tickets as  $y$ . The points form a line, so the function is linear.

**A third way:** Use an equation.

Linear equations can be written in the form  $y = mx + b$ , where  $m$  is the rate of change and  $b$  is the initial value.

Here, the rate of change  $m$  is the cost of each ticket, \$3, and the initial value  $b$  is the membership fee of \$50. Substituting 3 for  $m$  and 50 for  $b$  into  $y = mx + b$  gives  $y = 3x + 50$ . This equation is a linear equation.

**Answer:** All three methods show that the function representing the cost of tickets with a membership is a linear function.

### Vocabulary

**linear function** a function with a graph that is a non-vertical straight line, which can be represented by a linear equation in the form  $y = mx + b$ .
